6. Given: $|f(x+h)-f(x)| \le C|h|^{\alpha}$ for all $x,x+h \in (a,b)$. Assuming $h \ne 0$, we can write:

$$\left| \frac{f(x+h) - f(x)}{h} \right| \le C|h|^{\alpha - 1}$$

$$\implies -C|h|^{\alpha - 1} \le \frac{f(x+h) - f(x)}{h} \le C|h|^{\alpha - 1}$$

As $\alpha>1$, we have it that $\lim_{h\to 0}C|h|^{\alpha-1}=0$. Thus, by Sandwich Theorem, we have it that the limit $\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$ exists and is equal to 0. Thus, the function is differentiable, by definition.

By the definition of f'(x), we also have it that f'(x) = 0.

7.
$$\lim_{h \to 0^+} \frac{f(c+h) - f(c-h)}{2h} = \lim_{h \to 0^+} \frac{f(c+h) - f(c) + f(c) - f(c-h)}{2h}$$

Now, it is given that f is differentiable at c. This means that $\lim_{h\to 0^+} \frac{f(c+h)-f(c)}{h}$ exists. Moreover, it is equal to f'(c).

Similarly, the limit $\lim_{h\to 0^+} \frac{f(c)-f(c-h)}{h}$ exists and equals f'(c). Now that we know the existence of these limits, we can split the sum above.

$$\lim_{h \to 0^{+}} \frac{f(c+h) - f(c) + f(c) - f(c-h)}{2h}$$

$$= \frac{1}{2} \left(\lim_{h \to 0^{+}} \frac{f(c+h) - f(c)}{h} + \lim_{h \to 0^{+}} \frac{f(c) - f(c-h)}{h} \right)$$

$$= \frac{1}{2} \left(f'(c) + f'(c) \right) = f'(c).$$

(Converse.)

The converse need not be true. That is,

$$\lim_{h\to 0^+}\frac{f(c+h)-f(c-h)}{2h}$$

may exist but f could still be non-differentiable at c. Show this explicitly using f(x) := |x| as an example.

8. Given:
$$f(x + y) = f(x)f(y)$$
 for all $x, y \in \mathbb{R}$. (1)
Let $x = y = 0$. This gives us that $f(0) = (f(0))^2$.
Thus, $f(0) = 0$ or $f(0) = 1$.

Case 1. f(0) = 0.

Substitute y = 0 in (1). Thus, f(x) = f(0)f(x) = 0.

Therefore, f is identically 0 which means it's differentiable everywhere with derivative 0.

Verify that f'(c) = f'(0)f(c) does hold for all $x \in \mathbb{R}$. (We did not need to use the fact that f is differentiable at 0, it followed from definition.)

Case 2. f(0) = 1.

As f is differentiable at 0, we know that:

$$\lim_{h \to 0} \frac{f(0+h) - f(0)}{h} = f'(0) \implies \lim_{h \to 0} \frac{f(h) - 1}{h} = f'(0). \tag{2}$$

Now, let us show that f is differentiable everywhere.

Let $c \in \mathbb{R}$. We must show that the following limit exists:

$$\lim_{h\to 0}\frac{f(c+h)-f(c)}{h}$$

Using (1), we can write the above expression as:

$$\lim_{h \to 0} \frac{f(c)f(h) - f(c)}{h} = \lim_{h \to 0} \frac{f(c)(f(h) - 1)}{h} = f(c) \cdot \lim_{h \to 0} \frac{f(h) - 1}{h}.$$

By (2), we know that the above limit exists. Thus, we have it that f is differentiable at c for every $c \in \mathbb{R}$. Moreover, f'(c) = f'(0)f(c).

(**Optional**) We have gotten that the derivative of f is a scalar multiple of f. Use this to conclude.

9. (i) Let $f(x) := \cos x$ for $x \in (0, \pi)$. Then f is one-one and continuous. Consider $c \in (0, \pi)$. Now $f'(c) = -\sin c \neq 0$.

Further, $f\left((0,\pi)\right)=(-1,1)$. If $d\in(-1,1)$ and $f(c)=\cos c=d$, then

$$(f^{-1})'(d) = \frac{1}{f'(c)} = -\frac{1}{\sin c} = -\frac{1}{\sqrt{1-\cos^2 c}} = -\frac{1}{\sqrt{1-d^2}}.$$

(ii) Let $f(x) := \csc x$ for $x \in \left(-\frac{\pi}{2}, \frac{\pi}{2}\right) \setminus \{0\}$. Then f is one-one and continuous.

Consider $c \in \left(-\frac{\pi}{2}, \frac{\pi}{2}\right) \setminus \{0\}$. Now $f'(c) = -\csc c \cot c = -\csc^2 c \cos c \neq 0$.

Further, $f\left(\left(-\frac{\pi}{2},\frac{\pi}{2}\right)\setminus\{0\}\right)=(-\infty,-1)\cup(1,\infty)$. If |d|>1 and $f(c)=\csc c=d$, then

$$(f^{-1})'(d) = \frac{1}{f'(c)} = -\frac{1}{\csc^2 c \cos c} = -\frac{1}{\csc^2 c \sqrt{1 - \frac{1}{\csc^2 c}}} = -\frac{1}{|d|\sqrt{d^2 - 1}}.$$

10. Define $g(x) := \frac{2x-1}{x+1}$ for $x \in \mathbb{R} \setminus \{1\}$.

Given, $y = (f \circ g)(x)$. As g is differentiable in its domain and so is f, we know that $f \circ g$ is differentiable wherever defined and its derivative is given by:

$$\frac{dy}{dx} = (f \circ g)'(x) = f'(g(x))g'(x) = \sin\left((g(x))^2\right)g'(x).$$

Let us compute
$$g'(x)$$
. $g(x) = \frac{2x-1}{x+1} = \frac{2x+2-3}{x+1} = 2 - \frac{3}{x+1}$.

Using quotient rule, we get that $g'(x) = \frac{3}{(x+1)^2}$.

$$\therefore \frac{dy}{dx} = \sin\left(\left(\frac{2x-1}{x+1}\right)^2\right) \frac{3}{x+1}$$

- 2. Assume that the cubic (denote it by f(x)) has two roots, a and b. We may assume that a < b. Then, we know the following:
- (i) f is continuous on [a, b],
- (ii) f is differentiable on (a, b), and
- (iii) f(a) = f(b).

Thus, by Rolle's Theorem, there exists $c \in (a, b)$ such that f'(c) = 0.

However, $f'(c) = 3c^2 + p$ cannot be 0 as $3c^2$ is always non-negative and p is strictly positive.

Note: We have shown that the cubic has at most 1 root. We haven't actually shown that f has a root. This can be shown using IVT. (How?)

3. Part 1. We will first show the existence of such an $x_0 \in (a, b)$. Proof. I := [a, b] is an interval and f is continuous. Thus, f has the intermediate value property on I. Thus, the range J := f(I) must be an interval. As f(a) and f(b) are of different signs, 0 lies between them. As f(a), $f(b) \in J$ and J is an interval, we

Part 2. Now we will show the uniqueness of x_0 . Assume that there exists $x_1 \in (a, b)$ such that $f(x_1) = 0$. We may assume that $x_0 < x_1$.

Now, we know the following:

- (i) f is continuous on $[x_0, x_1]$,
- (ii) f is differentiable on (x_0, x_1) , and
- (iii) $f(x_0) = f(x_1)$.

Thus, by Rolle's Theorem, there exists $x_2 \in (x_0, x_1)$ such that $f'(x_2) = 0$. But this contradicts the hypothesis that $f'(x) \neq 0$ for all $x \in (a, b)$.

have it that $0 \in J = f(I)$. Thus, $0 = f(x_0)$ for some $x_0 \in I = (a, b)$.

Lagrange's Mean Value Theorem (MVT)

```
Theorem (MVT)
```

Let a < b and $f : [a, b] \to \mathbb{R}$ be a function such that

- (i) f is continuous on [a, b], and
- (ii) f is differentiable on (a, b).

Then there exists
$$c \in (a, b)$$
 such that $f'(c) = \frac{f(b) - f(a)}{b - a}$.

5. To prove that $|\sin a - \sin b| \le |a - b|$ for all $a, b \in \mathbb{R}$.

Case 1. a = b. Trivial.

Case 2. $a \neq b$. Without loss of generality, we can assume that a < b.

As $f := \sin is$ continuous and differentiable on \mathbb{R} , there exists $c \in (a,b)$ such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}.$$
 (By MVT)

Also, we know that $|f'(c)| = |\cos c| \le 1$.

Thus, we have it that $\left| \frac{f(b) - f(a)}{b - a} \right| \le 1$.

This is equivalent to what we wanted to prove.

6. Let $c := \frac{a+b}{2}$. It is clear that a < c < b. Moreover, we have it that 2(c-a) = 2(b-c) = b-a.

By MVT, there exists $c_1 \in (a,c)$ such that $f'(c_1) = \frac{f(c) - f(a)}{c-a}$ and there exists

 $c_2 \in (c,b)$ such that $f'(c_2) = \frac{f(b) - f(c)}{b-c}$. As c_1 and c_2 belong to disjoint intervals, it is clear that $c_1 \neq c_2$.

Observe that

$$f'(c_1) + f'(c_2) = \frac{f(c) - f(a)}{c - a} + \frac{f(b) - f(c)}{b - c} = 2\left(\frac{f(c) - f(a) + f(b) - f(c)}{b - a}\right) = 2. \blacksquare$$

8. Assume not. That is, $f(0) \neq 0$. Then, there are two possibilities.

Case 1. f(0) > 0.

The function f satisfies the hypothesis of MVT, thus there must exist $c \in (-a,0)$ such

that
$$f'(c) = \frac{f(0) - f(-a)}{0 - (-a)} = \frac{f(0)}{a} + 1$$
.

As f(0) > 0 and a > 0, we get that f'(c) > 1 which contradicts the hypothesis.

Case 2. f(0) < 0.

The function f satisfies the hypothesis of MVT, thus there must exist $d \in (0, a)$ such

that
$$f'(d) = \frac{f(a) - f(0)}{a - 0} = 1 - \frac{f(0)}{a}$$
.

As f(0) < 0 and a > 0, we get that f'(a) > 1 which contradicts the hypothesis.

(Optional) Note the following:

$$\frac{f(x) - f(-a)}{x - (-a)} = \frac{f(x) - x + x + a}{x + a} = \frac{f(x) - x}{x + a} + 1$$

and

$$\frac{f(a) - f(x)}{a - x} = \frac{a - x + x - f(x)}{a - x} = 1 + \frac{x - f(x)}{a - x}$$

Choose $x \in (-a, a)$ and use MVT appropriately to get contradictions for f(x) > x and f(x) < x.
